# Why Feature Engineering?

As always we love simple linear models

- Easy to analyze
- Unique solution

# Why Feature Engineering?

## As always we love simple linear models

- Easy to analyze
- Unique solution

## Definition

- Feature engineering (or feature extraction) is the process of using domain knowledge to extract features (characteristics, properties, attributes) from raw data.

# What is this?

## Main Question

“Given a number of features, how can one select the most important of them so as to reduce their number and at the same time retain as much as possible of their class discriminatory information? “

# What is this?

## Main Question

“Given a number of features, how can one select the most important of them so as to reduce their number and at the same time retain as much as possible of their class discriminatory information? “

## Why is important?

- 1 If we selected features with little discrimination power, the subsequent design of a classifier would lead to poor performance.

# What is this?

## Main Question

“Given a number of features, how can one select the most important of them so as to reduce their number and at the same time retain as much as possible of their class discriminatory information? “

## Why is important?

- 1 If we selected features with little discrimination power, the subsequent design of a classifier would lead to poor performance.
- 2 if information-rich features are selected, the design of the classifier can be greatly simplified.

# What is this?

## Main Question

## Why is important?

- 1 If we selected features with little discrimination power, the subsequent design of a classifier would lead to poor performance.
- 2 if information-rich features are selected, the design of the classifier can be greatly simplified.

## Therefore

We want features that lead to

- 1 Large between-class distance.

# What is this?

## Main Question

“Given a number of features, how can one select the most important of them so as to reduce their number and at the same time retain as much as possible of their class discriminatory information? “

## Why is important?

- ➊ If we selected features with little discrimination power, the subsequent design of a classifier would lead to poor performance.
- ➋ if information-rich features are selected, the design of the classifier can be greatly simplified.

## Therefore

We want features that lead to

- ➊ Large between-class distance.
- ➋ Small within-class variance.

Then

Basically, we want nice separated and dense clusters!!!

# Outliers

## Definition

An outlier is defined as a point that lies very far from the mean of the corresponding random variable.

# Outliers

## Definition

An outlier is defined as a point that lies very far from the mean of the corresponding random variable.

**Note:** We use the standard deviation

# Outliers

## Definition

An outlier is defined as a point that lies very far from the mean of the corresponding random variable.

**Note:** We use the standard deviation

## Example

For a normally distributed random

# Outliers

## Definition

An outlier is defined as a point that lies very far from the mean of the corresponding random variable.

**Note:** We use the standard deviation

## Example

For a normally distributed random

- 1 A distance of two times the standard deviation covers 95% of the points.

# Outliers

## Definition

An outlier is defined as a point that lies very far from the mean of the corresponding random variable.

**Note:** We use the standard deviation

## Example

For a normally distributed random

- 1 A distance of two times the standard deviation covers 95% of the points.
- 2 A distance of three times the standard deviation covers 99% of the points.

# Outliers

## Definition

An outlier is defined as a point that lies very far from the mean of the corresponding random variable.

**Note:** We use the standard deviation

## Example

For a normally distributed random

- ➊ A distance of two times the standard deviation covers 95% of the points.
- ➋ A distance of three times the standard deviation covers 99% of the points.

## Note

Points with values very different from the mean value produce large errors during training and may have disastrous effects. These effects are even worse when the outliers, and they are the result of noisy measureme

For example, we can use the standard deviation

For a set of samples  $x_1, x_2, x_3, \dots \in \mathbb{R}$

# Outlier Removal

## Important

Then removing outliers is the biggest importance.

# Outlier Removal

## Important

Then removing outliers is the biggest importance.

## Therefore

You can do the following

# Outlier Removal

## Important

Then removing outliers is the biggest importance.

## Therefore

You can do the following

- 1 If you have a small number  $\Rightarrow$  discard them!!!

# Outlier Removal

## Important

Then removing outliers is the biggest importance.

## Therefore

You can do the following

- 1 If you have a small number  $\Rightarrow$  discard them!!!
- 2 Adopt cost functions that are not sensitive to outliers:

# Outlier Removal

## Important

Then removing outliers is the biggest importance.

## Therefore

You can do the following

- 3 Find points  $O$  in  $M$  whose values are greater than

$$\chi_d^2(0.05)$$

# We can do the following

## Algorithm

**Input:** An  $N \times d$  data set  $Data$

**Output:** Candidate Outliers

- 1 Calculate the sample mean  $\mu$  and sample covariance matrix  $\Sigma$ .
- 2 Let  $M$  be  $N \times 1$  vector consisting of square of the Mahalanobis distance to  $\mu$ .
- 3 Find points  $O$  in  $M$  whose values are greater than

$$\chi_d^2(0.05)$$

- 4 Return  $O$ .

# How?

Get the Sample Mean per feature  $k$

$$m_i = \frac{1}{N} \sum_{k=1}^N x_{ki}$$

# How?

Get the Sample Mean per feature  $k$

$$\mathbf{m}_i = \frac{1}{N} \sum_{k=1}^N \mathbf{x}_{ki}$$

Get the Sample Variance per feature  $k$

$$v_i = \frac{1}{N-1} \sum_{k=1}^N (\mathbf{x}_{ki} - \mathbf{m}_i) (\mathbf{x}_{ki} - \mathbf{m}_i)^T$$

# Mahalanobis Distance

We have

$$M(\mathbf{x}) = \sqrt{(\mathbf{x} - \boldsymbol{\mu})^T \boldsymbol{\Sigma}^{-1} (\mathbf{x} - \boldsymbol{\mu})}$$

Thus

Setting  $M(x)$  to a constant  $c$  defines a multidimensional ellipsoid with centroid at  $\mu$

# Algorithm

## The Partial Code

```
def OutlierRemoval(self, Data):  
    SampleMean = Data.mean(1)  
    SampleCov = Data - SampleMean  
    SampleCov = np.cov(SampleCov.T)  
    Mahalonobis = (Data - SampleMean)*  
                   np.inv(SampleCov)*  
                   ((Data - SampleMean).T)  
  
    # Something else here  
    # Here you can use chi2.isf(\alpha,dim)
```

# Data Normalization

## In the real world

- In many practical situations a designer is confronted with features whose values lie within different dynamic ranges.

# Data Normalization

## In the real world

- In many practical situations a designer is confronted with features whose values lie within different dynamic ranges.

## For Example

- We can have two features with the following ranges

$$x_i \in [0, 100,000]$$

$$x_j \in [0, 0.5]$$

# Data Normalization

## In the real world

- In many practical situations a designer is confronted with features whose values lie within different dynamic ranges.

## For Example

- We can have two features with the following ranges

$$x_i \in [0, 100,000]$$

$$x_j \in [0, 0.5]$$

## Thus

- Many classification machines will be swamped by the first feature!!!

# Data Normalization

## We have the following situation

- Features with large values may have a larger influence in the cost function than features with small values.

# Data Normalization

## We have the following situation

- Features with large values may have a larger influence in the cost function than features with small values.

# Data Normalization

## We have the following situation

- Features with large values may have a larger influence in the cost function than features with small values.

## Thus!!!

- This does not necessarily reflect their respective significance in the design of the classifier.

# Outline

## 1 Introduction

- Feature Engineering

- What to do with it?
  - Sequential Backward Selection

## 3 Features Generation

- Introduction
- Principal Components
  - Projecting the Data
  - The PCA Process
  - Example

# Min-Max Method

## Be Naive

- For each feature  $i = 1, \dots, d$  obtain the  $\max_i$  and the  $\min_i$  such that

$$\hat{x}_{ik} = \frac{x_{ik} - \min_i}{\max_i - \min_i} \quad (1)$$

# Min-Max Method

## Be Naive

- For each feature  $i = 1, \dots, d$  obtain the  $\max_i$  and the  $\min_i$  such that

$$\hat{x}_{ik} = \frac{x_{ik} - \min_i}{\max_i - \min_i} \quad (1)$$

## Problem

- This simple normalization will send everything to a unitary sphere!!!
  - ▶ However, it works for certain type of data in Deep Learning

# However

Even though this can happen there have been reports that it can work...

- When data does not depend of single values as:

# Gaussian Method

Use the idea of

Everything is Gaussian...

# Gaussian Method

Use the idea of

Everything is Gaussian...

Thus

- For each feature set...

# Gaussian Method

Use the idea of

Everything is Gaussian...

Thus

- For each feature set...

$$\textcircled{1} \quad \bar{x}_k = \frac{1}{N} \sum_{i=1}^N x_{ik}, \quad k = 1, 2, \dots, d$$

# Gaussian Method

Use the idea of

Everything is Gaussian...

Thus

- For each feature set...

①  $\bar{x}_k = \frac{1}{N} \sum_{i=1}^N x_{ik}, \quad k = 1, 2, \dots, d$

②  $\sigma_k^2 = \frac{1}{N-1} \sum_{i=1}^N (x_{ik} - \bar{x}_k)^2, \quad k = 1, 2, \dots, d$

# Gaussian Method

Use the idea of

Everything is Gaussian...

Thus

- For each feature set...

$$\textcircled{1} \quad \bar{x}_k = \frac{1}{N} \sum_{i=1}^N x_{ik}, \quad k = 1, 2, \dots, d$$

$$\textcircled{2} \quad \sigma_k^2 = \frac{1}{N-1} \sum_{i=1}^N (x_{ik} - \bar{x}_k)^2, \quad k = 1, 2, \dots, d$$

Thus

$$\hat{x}_{ik} = \frac{x_{ik} - \bar{x}_k}{\sigma} \quad (2)$$

# Gaussian Method

Thus

- All new features have zero mean and unit variance.

# Gaussian Method

## Thus

- All new features have zero mean and unit variance.

## Further

- Other linear techniques limit the feature values in the range of  $[0, 1]$  or  $[-1, 1]$  by proper scaling.

# Gaussian Method

## Thus

- All new features have zero mean and unit variance.

## Further

- Other linear techniques limit the feature values in the range of  $[0, 1]$  or  $[-1, 1]$  by proper scaling.

## However

- We can non-linear mapping. For example the softmax scaling.

# Soft Max Scaling

## Softmax Scaling

- It consists of two steps

# Soft Max Scaling

## Softmax Scaling

- It consists of two steps

### First one

$$y_{ik} = \frac{x_{ik} - \bar{x}_k}{\sigma} \quad (3)$$

# Soft Max Scaling

## Softmax Scaling

- It consists of two steps

### First one

$$y_{ik} = \frac{x_{ik} - \bar{x}_k}{\sigma} \quad (3)$$

### Second one

$$\hat{x}_{ik} = \frac{1}{1 + \exp \{-y_{ik}\}} \quad (4)$$

# Explanation

Notice the red area is almost flat!!!

# Actually

Thus, we have that

- The red region represents values of  $y$  inside of the region defined by the mean and variance (small values of  $y$ ).
- Then, if we have those values  $x$  behaves as a linear function.

# Missing Data

## This can happen

In practice, certain features may be missing from some feature vectors.

# Missing Data

## This can happen

In practice, certain features may be missing from some feature vectors.

## Examples where this happens

- 1 Social sciences - incomplete surveys.

# Missing Data

## This can happen

In practice, certain features may be missing from some feature vectors.

## Examples where this happens

- 1 Social sciences - incomplete surveys.
- 2 Remote sensing - sensors go off-line.

# Missing Data

## This can happen

In practice, certain features may be missing from some feature vectors.

## Examples where this happens

- 1 Social sciences - incomplete surveys.
- 2 Remote sensing - sensors go off-line.
- 3 etc.

# Missing Data

## This can happen

In practice, certain features may be missing from some feature vectors.

## Examples where this happens

- 1 Social sciences - incomplete surveys.
- 2 Remote sensing - sensors go off-line.
- 3 etc.

## Note

Completing the missing values in a set of data is also known as imputation.

## Some traditional techniques to solve this problem

Use zeros and risked it!!!

The idea is not to add anything to the features

# Some traditional techniques to solve this problem

Use zeros and risked it!!!

The idea is not to add anything to the features

The sample mean/unconditional mean

Does not matter what distribution you have use the sample mean

$$\bar{x}_i = \frac{1}{N} \sum_{k=1}^N x_{ik} \quad (5)$$

# Some traditional techniques to solve this problem

Use zeros and risked it!!!

The idea is not to add anything to the features

The sample mean/unconditional mean

Does not matter what distribution you have use the sample mean

$$\bar{x}_i = \frac{1}{N} \sum_{k=1}^N x_{ik} \quad (5)$$

Find the distribution of your data

Use the mean from that distribution. For example, if you have a beta distribution

$$\bar{x}_i = \frac{\alpha}{\alpha + \beta} \quad (6)$$

# The MOST traditional

## Drop it

- Remove that data
  - ▶ Still you need to have a lot of data to have this luxury

# Outline

## 1 Introduction

  - Outlier Removal
  - Finding Multivariate Outliers
  - Data Normalization
  - Methods
- Missing Data
  - Matrix Completion
- The Peaking Phenomena

## 2 Feature Selection

- Feature Selection
- Considering Feature Sets
- Scatter Matrices
- What to do with it?
  - Sequential Backward Selection

## 3 Features Generation

- Introduction
- Principal Components
  - Projecting the Data
  - The PCA Process
  - Example

# Example

## We have two matrices

- Data Matrix  $X$
- Missing Data  $M$

$$M_{ij} = \begin{cases} 0 & X_{ij} \text{ is missing} \\ 1 & X_{ij} \text{ is not missing} \end{cases}$$

# Example

## We have two matrices

- Data Matrix  $X$
- Missing Data  $M$

$$M_{ij} = \begin{cases} 0 & X_{ij} \text{ is missing} \\ 1 & X_{ij} \text{ is not missing} \end{cases}$$

## Therefore, we have

- $X = (X_{obs}, X_{mis})$

# Example

We have two matrices

- Data Matrix  $X$
- Missing Data  $M$

$$M_{ij} = \begin{cases} 0 & X_{ij} \text{ is missing} \\ 1 & X_{ij} \text{ is not missing} \end{cases}$$

Therefore, we have

- $X = (X_{obs}, X_{mis})$

This comes from

- “Bayes and multiple imputation” by RJA Little, DB Rubin (2002)

We can use the following optimization

We can do the following

$$\min_{M_{ij}=1} \|X - AB\|_F$$

We can use the following optimization

We can do the following

$$\min_{M_{ij}=1} \|X - AB\|_F$$

Clearly an initial matrix decomposition, where

$$M_{ij}x_{ij} \approx \sum_{k=1}^K a_{ik}b_{kj}$$

We can use the following optimization

We can do the following

$$\min_{M_{ij}=1} \|X - AB\|_F$$

Clearly an initial matrix decomposition, where

$$M_{ij}x_{ij} \approx \sum_{k=1}^K a_{ik}b_{kj}$$

So the total error to be minimized is

$$\min_{M_{ij}=1} \|X - AB\|_F = \sqrt{\sum_{i=1}^N \sum_{j=1}^M \left[ M_{ij}x_{ij} - \sum_{k=1}^K a_{ik}b_{kj} \right]^2}$$

- $K \ll N, M$

This can be regularized

Using the following ideas

$$\min_{M_{ij}=1} \|X - AB\|_F + \lambda \left[ \|A\|^2 + \|B\|^2 \right]$$

This can be regularized

Using the following ideas

$$\min_{M_{ij}=1} \|X - AB\|_F + \lambda \left[ \|A\|^2 + \|B\|^2 \right]$$

Therefore, once the minimization is achieved

- We finish with two dense matrices  $A, B$  that can be used to obtain the elements with entries  $M_{ij} = 0$

# THE PEAKING PHENOMENON

## Remember

Normally, to design a classifier with good generalization performance, we want the number of sample  $N$  to be larger than the number of features  $d$ .

# THE PEAKING PHENOMENON

## Remeber

Normally, to design a classifier with good generalization performance, we want the number of sample  $N$  to be larger than the number of features  $d$ .

## What?

The intuition, the larger the number of samples vs the number of features, the smaller the error  $P_e$

# Graphically

For  $N_2 \gg N_1$

# The Goal of Feature Selection

## The Goal

- 1 Select the “optimum” number  $d$  of features.

# The Goal of Feature Selection

## The Goal

- 1 Select the “optimum” number  $d$  of features.
- 2 Select the “best”  $d$  features.

# The Goal of Feature Selection

## The Goal

- 1 Select the “optimum” number  $d$  of features.
- 2 Select the “best”  $d$  features.

## Why? Large $d$ has a three-fold disadvantage:

- High computational demands.

# The Goal of Feature Selection

## The Goal

- 1 Select the “optimum” number  $d$  of features.
- 2 Select the “best”  $d$  features.

## Why? Large $d$ has a three-fold disadvantage:

- High computational demands.
- Low generalization performance.

# The Goal of Feature Selection

## The Goal

- 1 Select the “optimum” number  $d$  of features.
- 2 Select the “best”  $d$  features.

## Why? Large $d$ has a three-fold disadvantage:

- High computational demands.
- Low generalization performance.
- Poor error estimates

# Feature Selection

Given  $N$

$d$  must be large enough to learn what makes classes different and what makes patterns in the same class similar

# Feature Selection

## Given $N$

$d$  must be large enough to learn what makes classes different and what makes patterns in the same class similar

## In addition

$d$  must be small enough not to learn what makes patterns of the same class different

# Feature Selection

## Given $N$

$d$  must be large enough to learn what makes classes different and what makes patterns in the same class similar

## In addition

$d$  must be small enough not to learn what makes patterns of the same class different

## In practice

In practice,  $d < N/3$  has been reported to be a sensible choice for a number of cases

Thus

Oh!!!

Once  $d$  has been decided, choose the  $d$  most informative features:

Thus

Oh!!!

Once  $d$  has been decided, choose the  $d$  most informative features:

**Best:** Large between class distance, Small within class variance.

Thus

Oh!!!

Once  $d$  has been decided, choose the  $d$  most informative features:

**Best:** Large between class distance, Small within class variance.

## The basic philosophy

- 1 Discard individual features with poor information content.

Thus

Oh!!!

Once  $d$  has been decided, choose the  $d$  most informative features:

**Best:** Large between class distance, Small within class variance.

## The basic philosophy

- 1 Discard individual features with poor information content.
- 2 The remaining information rich features are examined jointly as vectors

# Example

Thus, we want to avoid choices

# Example

## Better Choice

# Example

## What We Want to Have

# Outline

## 1 Introduction

- Feature Engineering
- What is Feature Selection?
- Preprocessing
  - Outlier Removal
  - Finding Multivariate Outliers
  - Data Normalization
  - Methods
- Missing Data
  - Matrix Completion
- The Peaking Phenomena

## 2 Feature Selection

- Feature Selection
- Considering Feature Sets
- Scatter Matrices
- What to do with it?
  - Sequential Backward Selection

## 3 Features Generation

- Introduction
- Principal Components
  - Projecting the Data
  - The PCA Process
  - Example

# Considering Feature Sets

## Something Notable

- The emphasis so far was on individually considered features.

# Considering Feature Sets

## Something Notable

- The emphasis so far was on individually considered features.

## But

- That is, two features may be rich in information, but if they are highly correlated we need not consider both of them.

# Considering Feature Sets

## Something Notable

- The emphasis so far was on individually considered features.

## But

- That is, two features may be rich in information, but if they are highly correlated we need not consider both of them.

## Then

- Combine features to search for the “best” combination after features have been discarded.

# What to do?

## Possible

- Use different feature combinations to form the feature vector.

# What to do?

## Possible

- Use different feature combinations to form the feature vector.
- Train the classifier, and choose the combination resulting in the best classifier performance.

# What to do?

## Possible

- Use different feature combinations to form the feature vector.
- Train the classifier, and choose the combination resulting in the best classifier performance.

## However

- A major disadvantage of this approach is the high complexity.

# What to do?

## Possible

- Use different feature combinations to form the feature vector.
- Train the classifier, and choose the combination resulting in the best classifier performance.

## However

- A major disadvantage of this approach is the high complexity.
- Also, local minimum may give misleading results.

# What to do?

## Possible

- Use different feature combinations to form the feature vector.
- Train the classifier, and choose the combination resulting in the best classifier performance.

## However

- A major disadvantage of this approach is the high complexity.
- Also, local minimum may give misleading results.

## Better

- Adopt a class separability measure and choose the best feature combination against this cost.

# Scatter Matrices

## Definition

- These are used as a measure of the way data are scattered in the respective feature space.

# Scatter Matrices

## Definition

- These are used as a measure of the way data are scattered in the respective feature space.

## Within-class Scatter Matrix

$$S_w = \sum_{i=1}^C P_i S_i \quad (7)$$

- where  $C$  is the number of classes.

# Scatter Matrices

## Definition

- These are used as a measure of the way data are scattered in the respective feature space.

## Within-class Scatter Matrix

$$S_w = \sum_{i=1}^C P_i S_i \quad (7)$$

- where  $C$  is the number of classes.

where

①  $S_i = E \left[ (\mathbf{x} - \boldsymbol{\mu}_i) (\mathbf{x} - \boldsymbol{\mu}_i)^T \right]$

# Scatter Matrices

## Definition

- These are used as a measure of the way data are scattered in the respective feature space.

## Within-class Scatter Matrix

$$S_w = \sum_{i=1}^C P_i S_i \quad (7)$$

- where  $C$  is the number of classes.

where

- $S_i = E \left[ (\mathbf{x} - \boldsymbol{\mu}_i) (\mathbf{x} - \boldsymbol{\mu}_i)^T \right]$
- $P_i$  the a priori probability of class  $\omega_i$  defined as  $P_i \cong n_i/N$ .

# Scatter Matrices

## Definition

- These are used as a measure of the way data are scattered in the respective feature space.

## Within-class Scatter Matrix

$$S_w = \sum_{i=1}^C P_i S_i \quad (7)$$

- where  $C$  is the number of classes.

where

- 1  $S_i = E \left[ (\mathbf{x} - \boldsymbol{\mu}_i) (\mathbf{x} - \boldsymbol{\mu}_i)^T \right]$
- 2  $P_i$  the a priori probability of class  $\omega_i$  defined as  $P_i \cong n_i/N$ .
  - 1  $n_i$  is the number of samples in class  $\omega_i$ .

# Scatter Matrices

## Between-class scatter matrix

$$S_b = \sum_{i=1}^C P_i (\mathbf{x} - \boldsymbol{\mu}_0) (\mathbf{x} - \boldsymbol{\mu}_0)^T \quad (8)$$

# Scatter Matrices

## Between-class scatter matrix

$$S_b = \sum_{i=1}^C P_i (\mathbf{x} - \boldsymbol{\mu}_0) (\mathbf{x} - \boldsymbol{\mu}_0)^T \quad (8)$$

## Where

$$\boldsymbol{\mu}_0 = \sum_{i=1}^C P_i \boldsymbol{\mu}_i \quad (9)$$

The global mean.

# Scatter Matrices

## Between-class scatter matrix

$$S_b = \sum_{i=1}^C P_i (\mathbf{x} - \boldsymbol{\mu}_0) (\mathbf{x} - \boldsymbol{\mu}_0)^T \quad (8)$$

Where

$$\boldsymbol{\mu}_0 = \sum_{i=1}^C P_i \boldsymbol{\mu}_i \quad (9)$$

The global mean.

## Mixture scatter matrix

$$S_m = E \left[ (\mathbf{x} - \boldsymbol{\mu}_0) (\mathbf{x} - \boldsymbol{\mu}_0)^T \right] \quad (10)$$

**Note:** it can be proved that  $S_m = S_w + S_b$

# Criterion's

## First One

$$J_1 = \frac{\text{trace}\{S_m\}}{\text{trace}\{S_w\}} \quad (11)$$

- It takes large values when samples in the  $d$ -dimensional space are well clustered around their mean, within each class, and the clusters of the different classes are well separated.

# Criterion's

## First One

$$J_1 = \frac{\text{trace}\{S_m\}}{\text{trace}\{S_w\}} \quad (11)$$

- It takes large values when samples in the  $d$ -dimensional space are well clustered around their mean, within each class, and the clusters of the different classes are well separated.

## Other Criteria are

1  $J_2 = \frac{|S_m|}{|S_w|}$

# Criterion's

## First One

$$J_1 = \frac{\text{trace} \{S_m\}}{\text{trace} \{S_w\}} \quad (11)$$

- It takes large values when samples in the  $d$ -dimensional space are well clustered around their mean, within each class, and the clusters of the different classes are well separated.

## Other Criteria are

- 1  $J_2 = \frac{|S_m|}{|S_w|}$
- 2  $J_3 = \text{trace} \{S_w^{-1} S_m\}$

# Example

## We have

- Classes with
  - ▶ (a) small within-class variance and small between-class distances,
  - ▶ (b) large within- class variance and small between-class distances,
  - ▶ (c) small within-class variance and large between-class distances.

(a)

(b)

(c)

    - Example

## For example: Sequential Backward Selection

We have the following example

Given  $x_1, x_2, x_3, x_4$  and we wish to select two of them

## For example: Sequential Backward Selection

We have the following example

Given  $x_1, x_2, x_3, x_4$  and we wish to select two of them

### Step 1

Adopt a class separability criterion,  $C$ , and compute its value for the feature vector  $[x_1, x_2, x_3, x_4]^T$ .

# For example: Sequential Backward Selection

We have the following example

Given  $x_1, x_2, x_3, x_4$  and we wish to select two of them

## Step 1

Adopt a class separability criterion,  $C$ , and compute its value for the feature vector  $[x_1, x_2, x_3, x_4]^T$ .

## Step 2

Eliminate one feature, you get

$$[x_1, x_2, x_3]^T, [x_1, x_2, x_4]^T, [x_1, x_3, x_4]^T, [x_2, x_3, x_4]^T,$$

## For example: Sequential Backward Selection

You use your criterion  $C$

Thus the winner is  $[x_1, x_2, x_3]^T$

## For example: Sequential Backward Selection

You use your criterion  $C$

Thus the winner is  $[x_1, x_2, x_3]^T$

### Step 3

Now, eliminate a feature and generate  $[x_1, x_2]^T, [x_1, x_3]^T, [x_2, x_3]^T,$

## For example: Sequential Backward Selection

You use your criterion  $C$

Thus the winner is  $[x_1, x_2, x_3]^T$

### Step 3

Now, eliminate a feature and generate  $[x_1, x_2]^T, [x_1, x_3]^T, [x_2, x_3]^T,$

Use criterion  $C$

To select the best one

# Complexity of the Method

## Complexity

Thus, starting from  $m$ , at each step we drop out one feature from the “best” combination until we obtain a vector of  $l$  features.

# Complexity of the Method

## Complexity

Thus, starting from  $m$ , at each step we drop out one feature from the “best” combination until we obtain a vector of  $l$  features.

Thus, we need

$1 + 1/2((m + 1)m - l(l + 1))$  combinations

# Complexity of the Method

## Complexity

Thus, starting from  $m$ , at each step we drop out one feature from the “best” combination until we obtain a vector of  $l$  features.

## Thus, we need

$1 + 1/2((m + 1)m - l(l + 1))$  combinations

## However

- The method is sub-optimal

# Complexity of the Method

Thus, Can we get more powerful mappings?

- To obtain better features

# Did you noticed?

That Rotations really do not exist

- Actually, they are mappings or projections in linear algebra

Thus, Can we get more powerful mappings?

- To obtain better features

Clearly... Yes

- For example, Principal Components

## Also Known as Karhunen-Loeve Transform

### Setup

- Consider a data set of observations  $\{x_n\}$  with  $n = 1, 2, \dots, N$  and  $x_n \in R^d$ .

# Also Known as Karhunen-Loeve Transform

## Setup

- Consider a data set of observations  $\{x_n\}$  with  $n = 1, 2, \dots, N$  and  $x_n \in R^d$ .

## Goal

Project data onto space with dimensionality  $m < d$  (We assume  $m$  is given)

# Basically

## Principal Component Analysis

- Attempts to maximize the variance in certain vectors

# Basically

## Principal Component Analysis

- Attempts to maximize the variance in certain vectors

## Basically Linear Algebra

- Basically discover the basis that describe best the data dispersion in specific directions

## Now, Define

Given the data

$$\mathbf{x}_1, \mathbf{x}_2, \dots, \mathbf{x}_N \quad (12)$$

where  $\mathbf{x}_i$  is a column vector

## Now, Define

Given the data

$$\mathbf{x}_1, \mathbf{x}_2, \dots, \mathbf{x}_N \quad (12)$$

where  $\mathbf{x}_i$  is a column vector

Construct the sample mean

$$\bar{\mathbf{x}} = \frac{1}{N} \sum_{i=1}^N \mathbf{x}_i \quad (13)$$

## Now, Define

Given the data

$$\mathbf{x}_1, \mathbf{x}_2, \dots, \mathbf{x}_N \quad (12)$$

where  $\mathbf{x}_i$  is a column vector

Construct the sample mean

$$\bar{\mathbf{x}} = \frac{1}{N} \sum_{i=1}^N \mathbf{x}_i \quad (13)$$

Center data

$$\mathbf{x}_1 - \bar{\mathbf{x}}, \mathbf{x}_2 - \bar{\mathbf{x}}, \dots, \mathbf{x}_N - \bar{\mathbf{x}} \quad (14)$$

# Build the Sample Mean

## The Covariance Matrix

$$S = \frac{1}{N-1} \sum_{i=1}^N (\mathbf{x}_i - \bar{\mathbf{x}}) (\mathbf{x}_i - \bar{\mathbf{x}})^T \quad (15)$$

# Build the Sample Mean

## The Covariance Matrix

$$S = \frac{1}{N-1} \sum_{i=1}^N (\mathbf{x}_i - \bar{\mathbf{x}}) (\mathbf{x}_i - \bar{\mathbf{x}})^T \quad (15)$$

## Properties

- 1 The  $ij$ th value of  $S$  is equivalent to  $\sigma_{ij}^2$ .
- 2 The  $ii$ th value of  $S$  is equivalent to  $\sigma_{ii}^2$ .

We have the following steps

Determine covariance matrix

$$S = \frac{1}{N-1} \sum_{i=1}^N (\mathbf{x}_i - \bar{\mathbf{x}}) (\mathbf{x}_i - \bar{\mathbf{x}})^T \quad (16)$$

We have the following steps

Determine covariance matrix

$$S = \frac{1}{N-1} \sum_{i=1}^N (\mathbf{x}_i - \bar{\mathbf{x}}) (\mathbf{x}_i - \bar{\mathbf{x}})^T \quad (16)$$

Generate the decomposition

$$S = U \Sigma U^T$$

We have the following steps

Determine covariance matrix

$$S = \frac{1}{N-1} \sum_{i=1}^N (\mathbf{x}_i - \bar{\mathbf{x}}) (\mathbf{x}_i - \bar{\mathbf{x}})^T \quad (16)$$

Generate the decomposition

$$S = U \Sigma U^T$$

With

- Eigenvalues in  $\Sigma$  and eigenvectors in the columns of  $U$ .

Then

Project samples  $\mathbf{x}_i$  into subspaces  $\text{dim}=k$

$$z_i = U_K^T \mathbf{x}_i$$

- With  $U_k$  is a matrix with  $k$  columns
